

ICRP TG108 Workshop

*Optimisation of Radiological Protection in Digital Radiology Techniques for Medical Imaging
26th - 27th October 2022, Virtual meeting, hosted by ICRP*

Building optimisation into routine practice

Mika Kortnesniemi

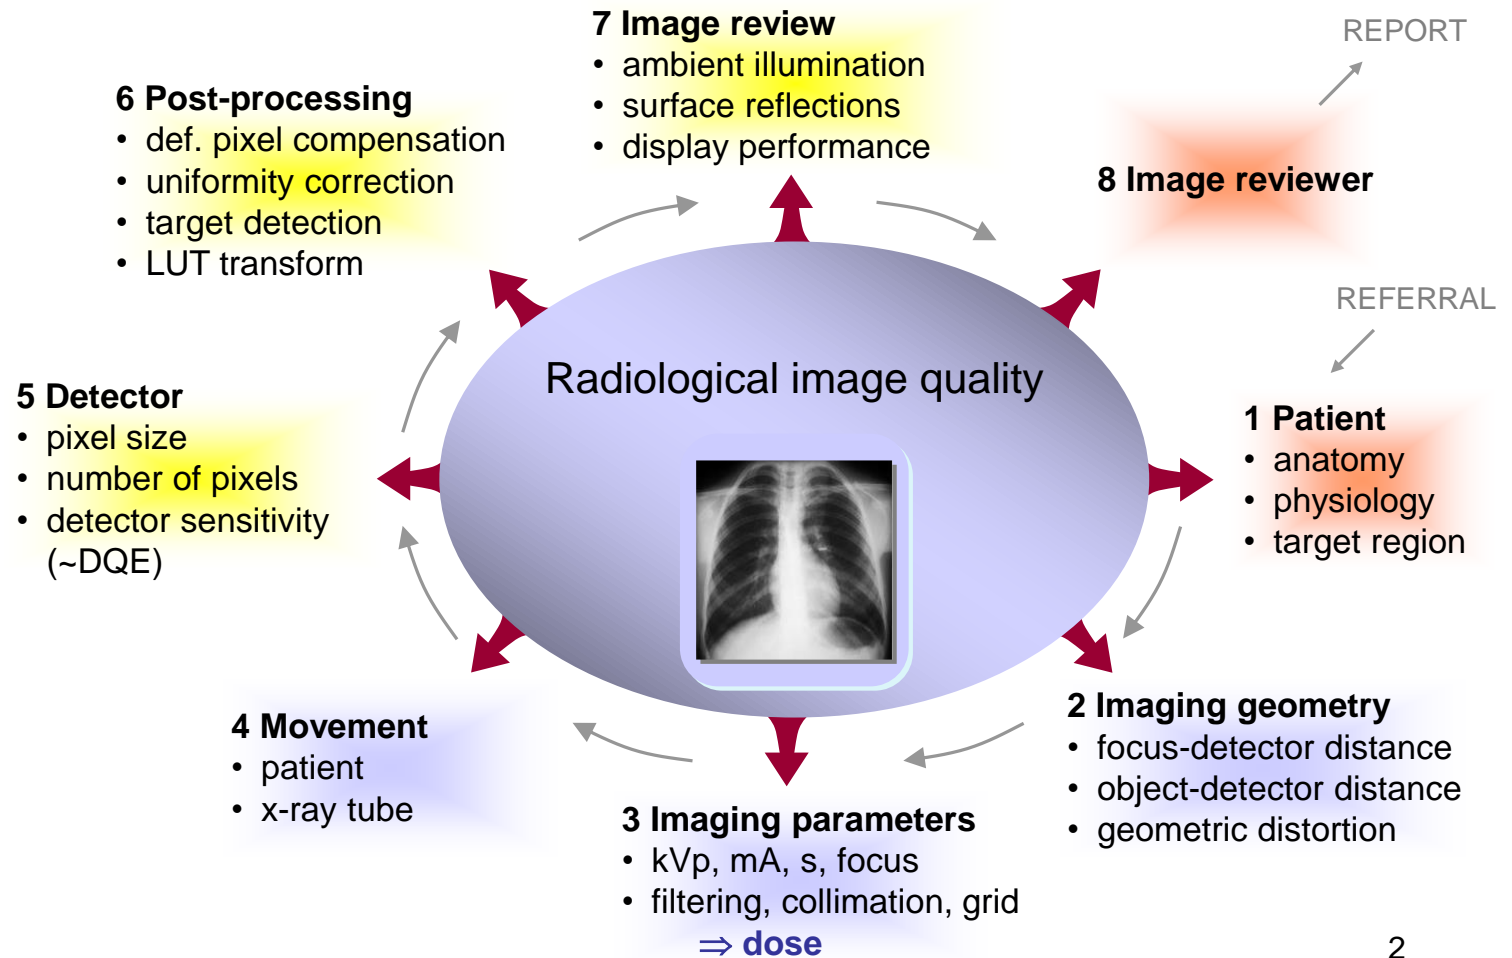

Chief medical Physicist, Adjunct Professor, PhD

**HUS Diagnostic Center, University of Helsinki and Helsinki
University Hospital, Finland**

ICRP Committee 3 on Protection in Medicine

Factors affecting dose and image quality in digital imaging

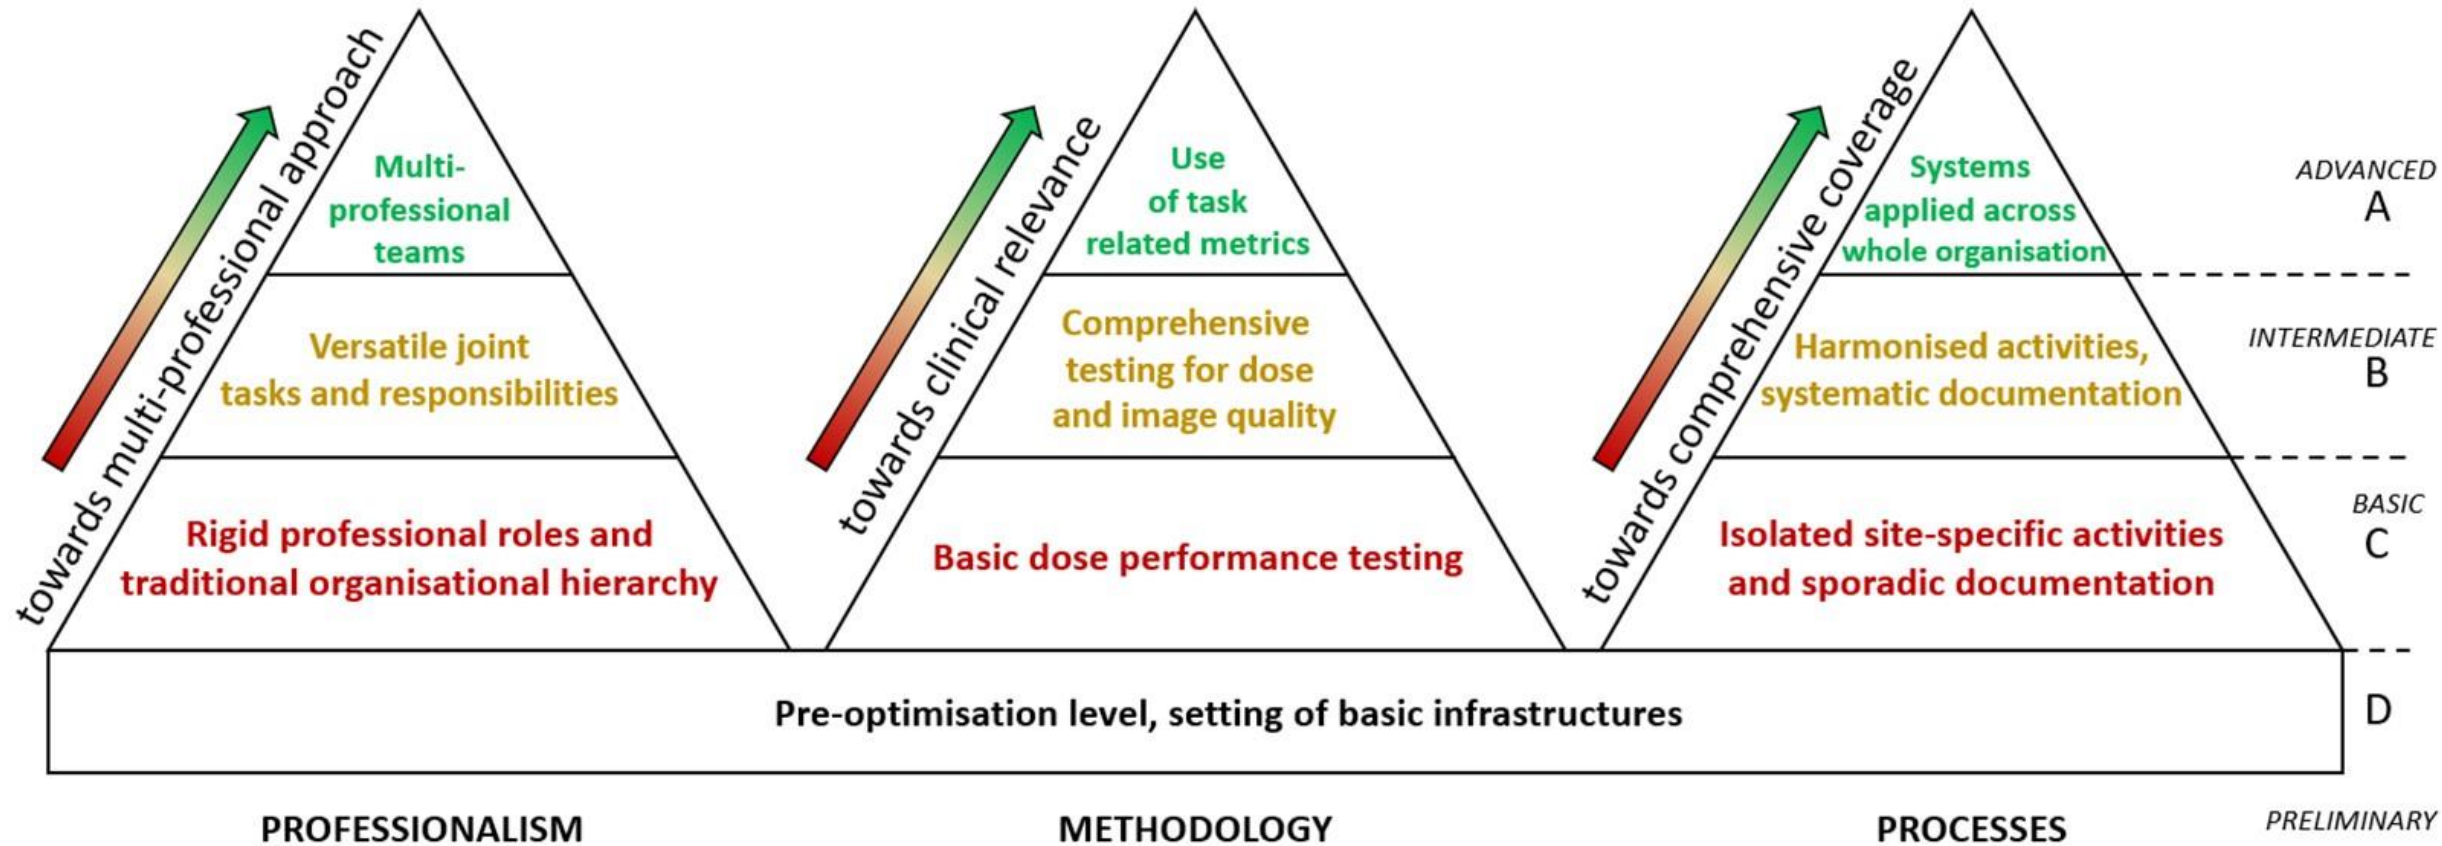

The clinical value of images is dependent on physical characteristics of the imaging method (~medical physicist), image capture and presentation system (~radiographer) and the interpreter (~radiologist).

The whole imaging chain and process must be evaluated

Components and levels required for continuously improving optimisation

Within each component, levels of achieved performance will vary in different organisations.

Radiological professionals working together

C. Basic: Radiologists, radiographers, and medical physicists perform roles separately and independently of each other.

Establishing Diagnostic Reference Levels (DRLs) is involved in move from level C to B.

B. Intermediate: Optimisation Teams comprising radiographers, radiologists, and medical physicists established.

Comparison of dose survey results with DRLs, followed by review and optimise protocols for some modalities

A. Advanced: The whole Optimisation Team is involved in regular review of clinical protocols for all modalities.

Example of dose monitoring annual cycle plan

Comparing patient doses vs DRLs

Multiprofessionality in optimisation

It's not just about primary diagnostics. Differential diagnostics and incidental findings matter as well.

Indication ⇒ *Clinical image quality*

Sensitivity

Specificity

Quality assurance

Dosimetry

Patient safety

Imaging parameters
⇒ *resolution, contrast, noise, dose*

Imaging equipment & work methods

Operation of digital x-ray equipment

- Successful operation of digital x-ray equipment requires **high levels of knowledge and skill** from clinicians, radiographers and medical physicists.
- Settings should be agreed by members of the **multi-professional** imaging team and **documented** in protocols
- All members of the team must be given the necessary expertise through **training and experience**
- **Training must be updated** regularly, so everyone fully understands equipment operation

Take full advantage of user training

It's not just a system – require also the functionality and optimised protocols

Qualifiers of successful optimisation

- **Ongoing, forward-looking, iterative process** ⇒ **continuous improvements** with quantitative and qualitative evaluation.
- **Systematic and carefully structured** to ensure that all relevant aspects in the diagnostic chain are taken into account.
- Requires **commitment at all levels** as well as **adequate procedures and resources** in organisations.
- **Optimisation is not minimisation of dose** – it's a question of balance; the best option is not necessarily the one with the lowest dose.

Two levels of optimisation

Regular review of every aspect of the imaging process is key to the successful achievement of optimisation.

- 1) The **design and construction** of the equipment and the installation
- 2) The **day-to-day working procedures** performed by the staff involved

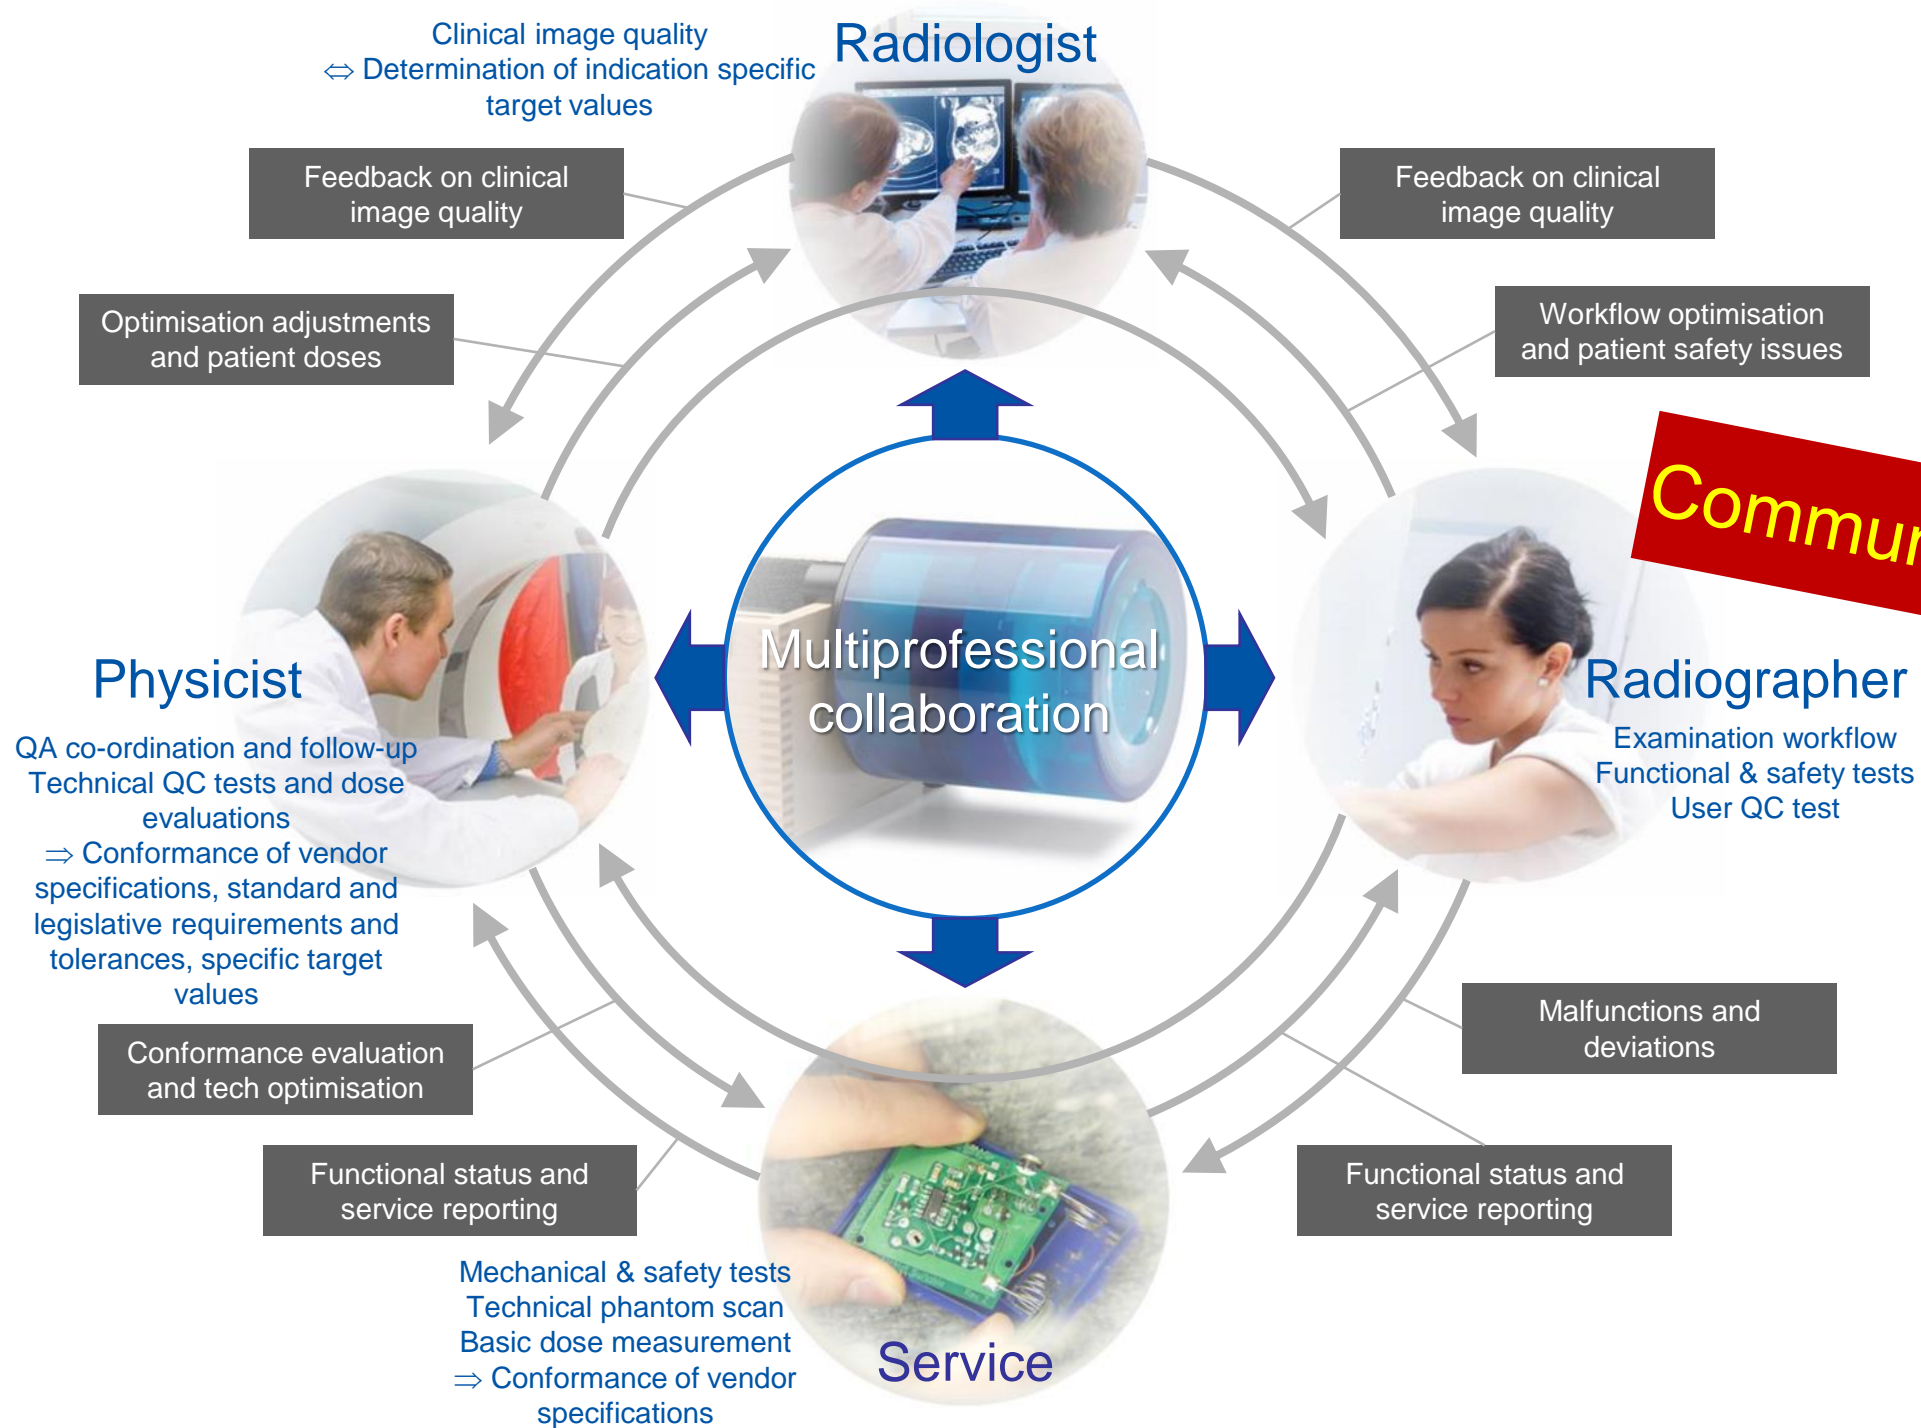

Optimisation will only occur if:

- 1) All staff are **properly trained** in their roles
- 2) Equipment operation is ensured through a **comprehensive QA programme**
- 3) There is **ongoing monitoring**, review, and analysis of performance
- 4) This feeds back into **continual improvement** of protocols.

Practical multiprofessional optimisation during commissioning

- C: Set the basic parameters
- B: Adjust indication specific parameters to maximise image quality per dose unit (e.g. spectral optimisation)
- A: Adjust patient-specific parameters (typically mAs by ATCM) in individual exams to achieve diagnostic image quality with the lowest dose
- Harmonise protocols (incl. exposure parameters) in order to achieve consistent image quality throughout the organisation

Main directions of developing methods

reducing variability
Consistency

Quality
on average

Main directions of developing methods

reducing variability

Quality
on average

**Clinical
relevance**

**Technical
performance**

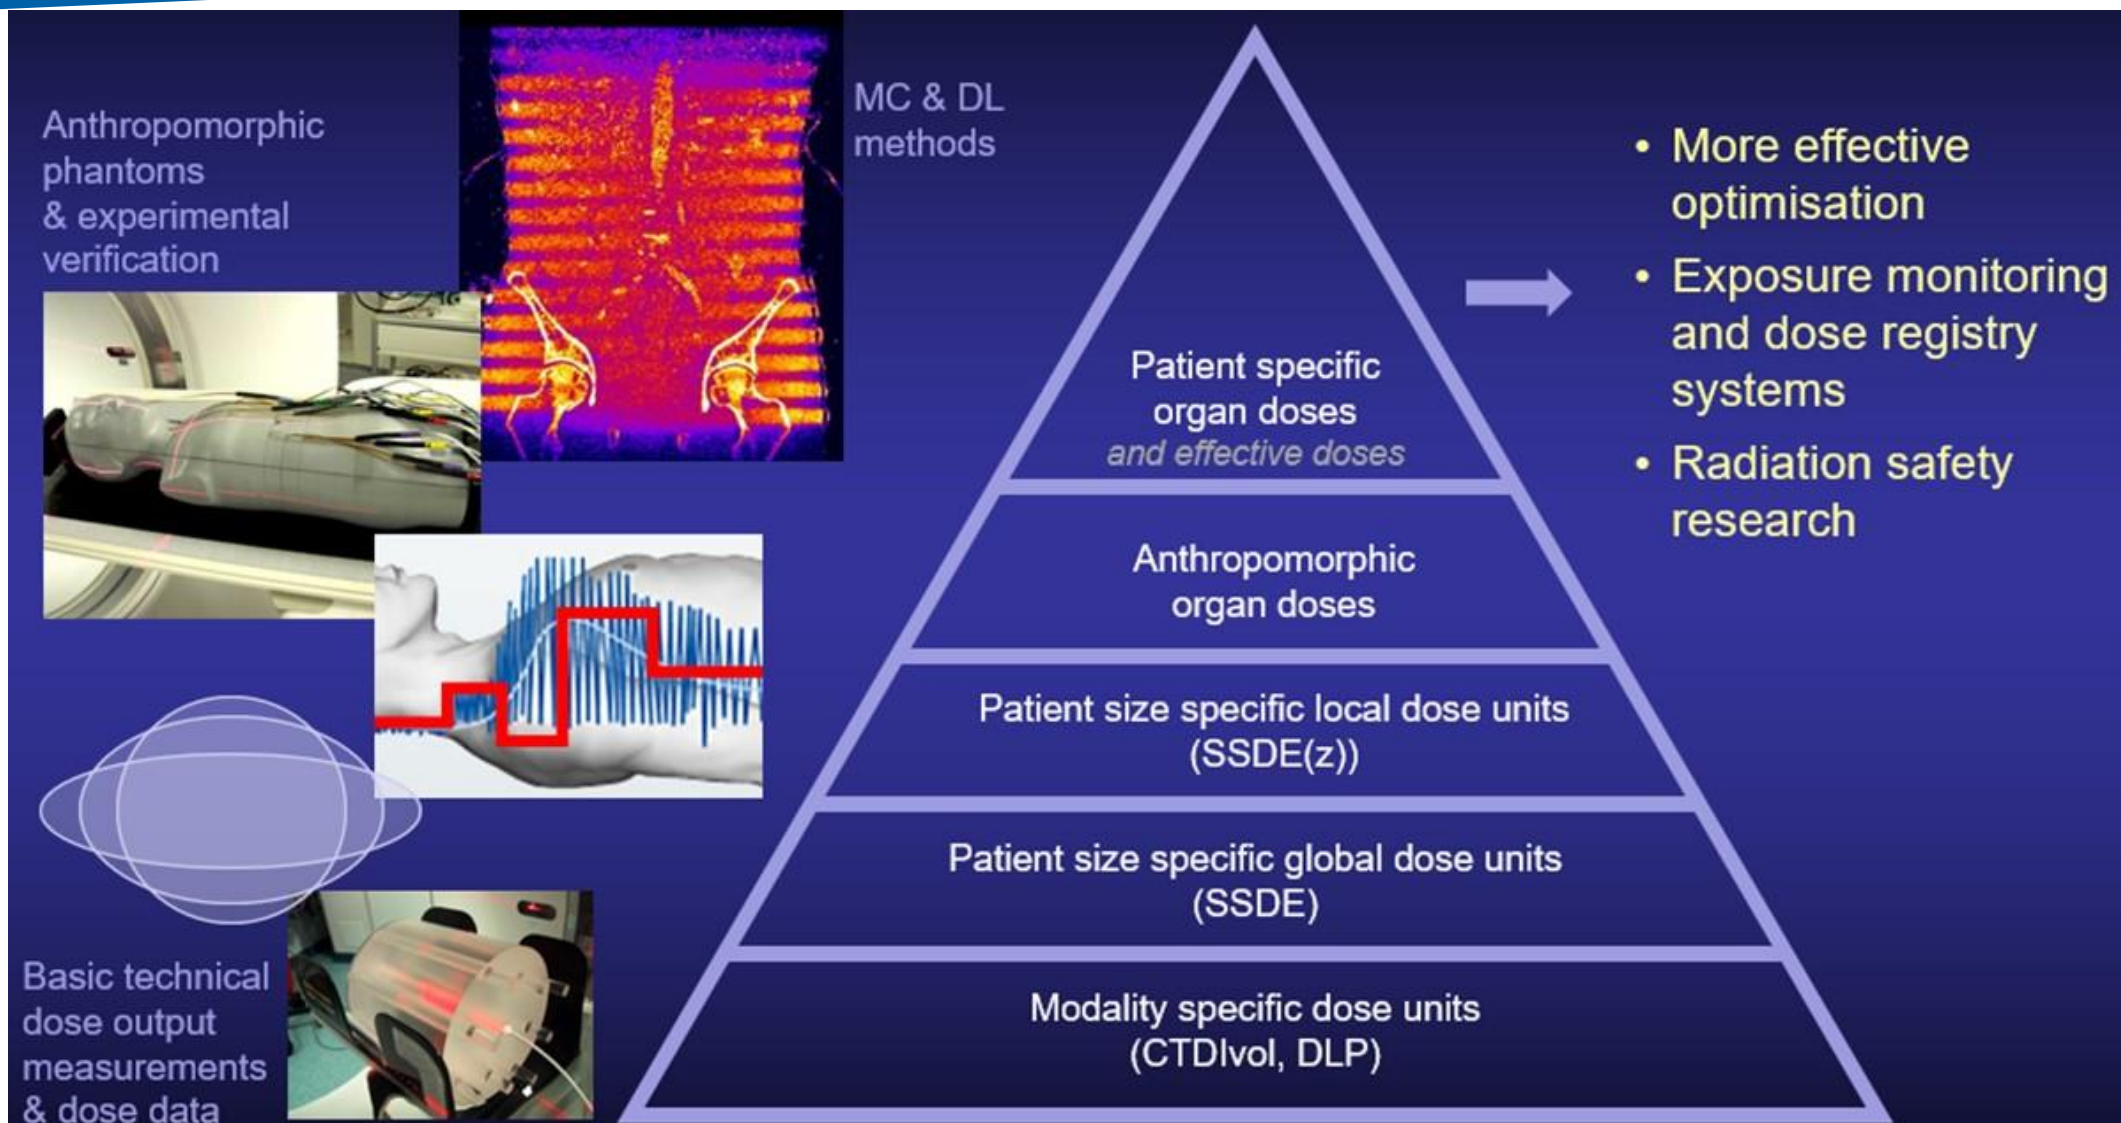

Utilising anthropomorphic models in optimisation ⇒ Aiming closer to clinical cases

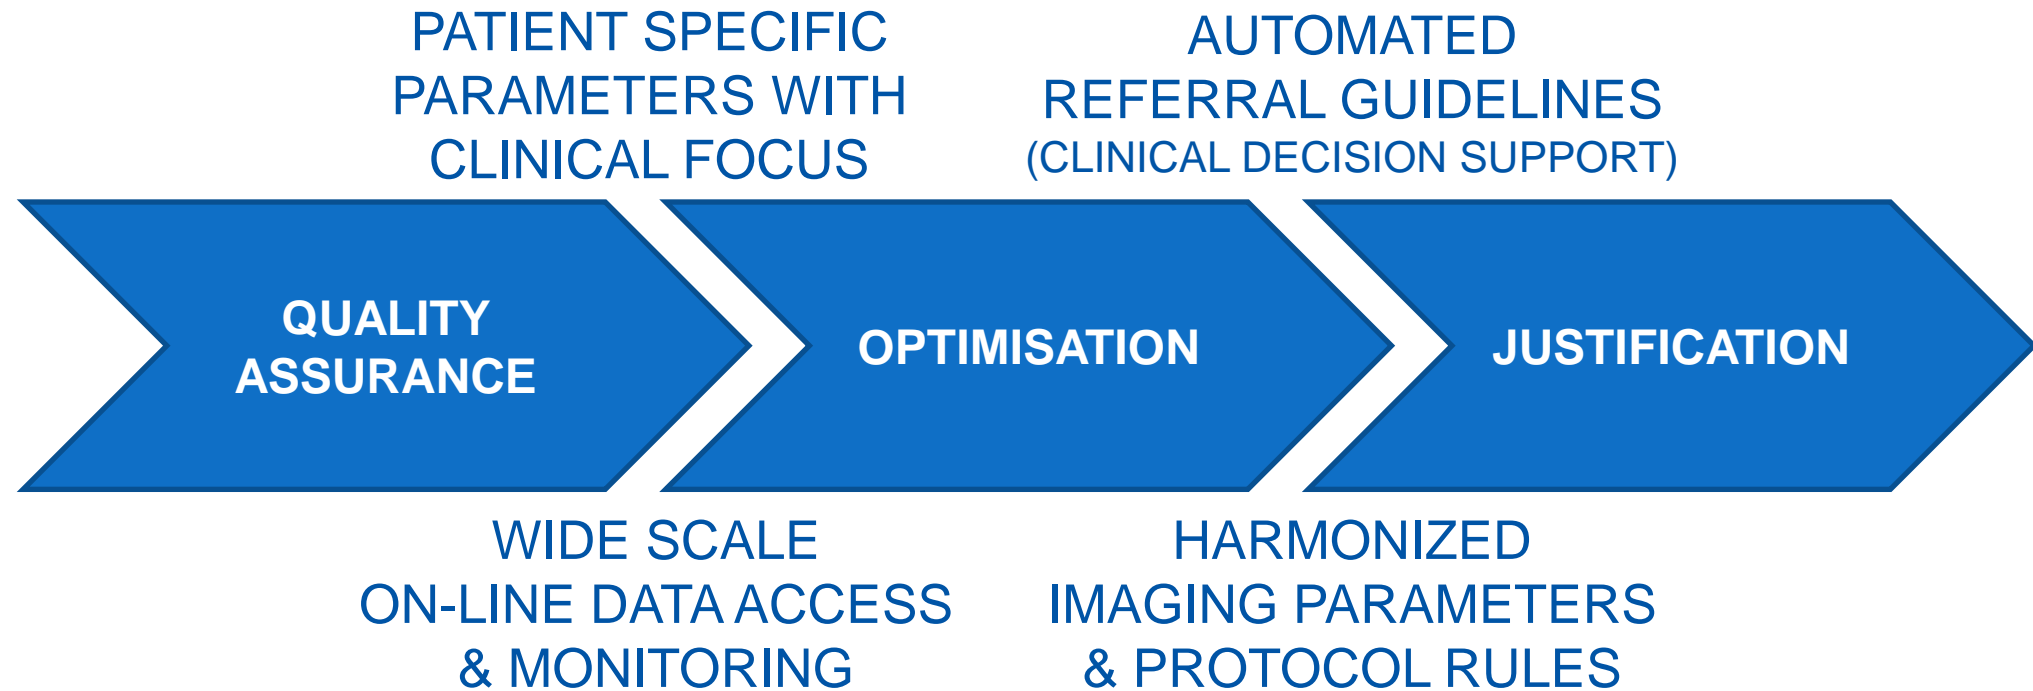

Example of anatomical & indication based DRLs (for CT in Finland)

Examination type or indication	CTDI _{vol} mGy	DLP mGy·cm
Head/brain	55	800
Sinuses	13	190
Chest	9	290
Abdomen	12	560
Body	12	770
Aorta (neck to groin)	10	630
Indication - HRCT	5	140
Indication - lung tumour	11	430
Indication - renal stones	7	330
Indication - lymphoma	11	970
Indication - trauma body	17	1300
Indication - colonoscopy (prone)	6.5	total from both positions: 930
Indication - colonoscopy (supine)	12	

Towards patient-specific dosimetry – example: CT

Gradual unification of core RP components by evolving methods and processes

Evolved QA methods enable more effective patient-specific optimisation with clinical relevance

Automated referral guidance and procoling connect optimisation and justification more closely together

An iceberg floating in a blue ocean under a blue sky. The tip of the iceberg is above the water, while the much larger, jagged base is submerged. The text is overlaid on the image, with the top part above the water and the bottom part below. The central text is in yellow, while the other text is in white or light blue.

Formal policy - mission, vision and strategy, systems and practices

Informal practices and **culture**

Culture eats strategy for lunch every day.

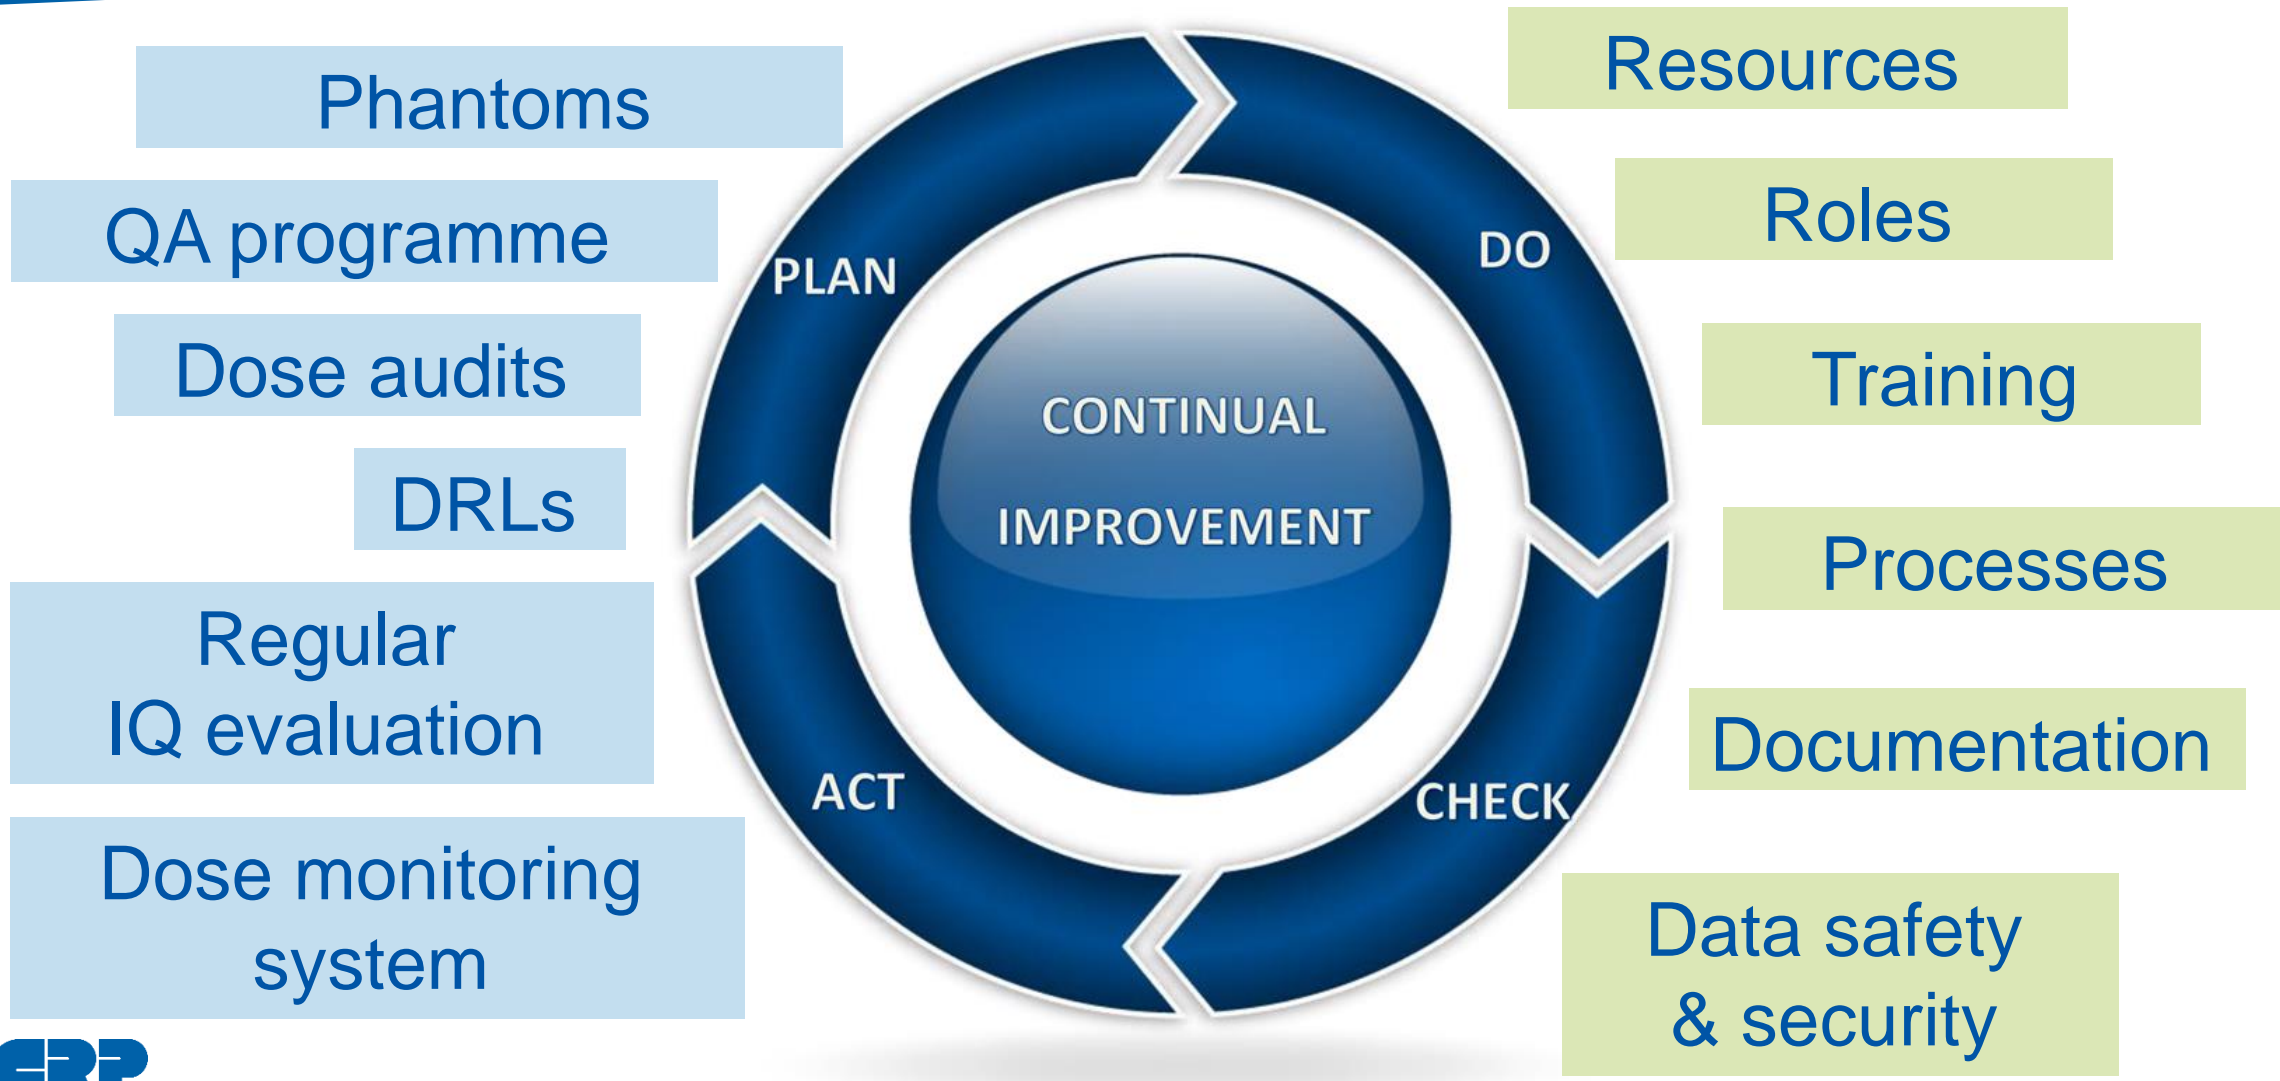

Beliefs, values and attitudes

When you aim for improvements by planning and doing, also check the the outcome systematically to reach effective outcome

“What if we don’t change at all ...
and something magical just happens?”

Importance of continual improvement
