Abstract— Digital Radiology introduced benefits to the medical imaging practices and enhanced the quality of services provided to patients. This paper discusses the major differences between Digital Radiology and Conventional Radiology with emphasis on methodologies followed to estimate patient radiation doses. It presents the current details on the trends in diagnostic patient dose registries and dose guidance levels applied in the digital diagnostic and interventional radiology practices. The practical impact of the new recommendations of the International Commission on Radiological Protection (ICRP) is highlighted to specify the current challenging points in the practice of radiation protection in medicine. Considering the latest ICRP recommendations and the advances in digital radiology, the importance of patient dose recording and the establishment of Diagnostic Reference Levels (DRLs) for digital radiology are indicated. Dubai Health Authority (DHA) experience in establishing local DRLs are presented along with dose guidance values published internationally. The DHA participated in national and regional projects under the umbrella of the International Atomic Energy Agency (IAEA). The necessity for local radiation protection educational programs and patient dosimetry monitoring and recording were emerged from our patient radiation dosimetry projects. These are considered as essential requirements to prompt radiation safety culture within the various healthcare communities.

Keywords: Radiation Dose, Digital Radiology, Dosimetry, Dose Registry, Dose Reference Levels, DRL
- Differences: Digital and Conventional Radiology

- Radiation Doses: Patient Dose Registry and DRL

- Dubai Health Authority (DHA) Experience
Review:

Â ICRP Publication 60, 1991, Diagnostic Reference Levels (DRLs), which are a form of investigation levels to optimize image quality and the radiation dose delivered to patients.

Â DRL concept was further expanded in ICRP Publication 73, 1996

Â BSS 115, 1996 Guidance Levels

Â ICRP, 2001 (Review and Additional advice) on applications of DRL in digital and interventional Radiology.

Â ICRP Publication 121, on RP in Paediatric Diagnostic and Interventional Radiology, 2013

Diagnostic reference level

Used in medical imaging with ionizing radiation to indicate whether, in routine conditions, the patient dose or administered activity (amount of radioactive material) from a specified procedure is unusually high or low for that procedure.

ICRP, Report 103, 2007
ICRP Publication – 121, 2013

(f) The development and regular updating of local, regional, or national diagnostic reference levels (DRLs) to assist in the optimisation process is encouraged. Also, regular audits of referral criteria, imaging quality, and imaging technique should be implemented as part of the radiological protection culture.

(38) ICRP does not specify quantities, numerical values, or details of implementation for DRLs. This is the task of the regional, national, and local authorised bodies, each of which should meet the needs in their respective areas.
Quantities used for DRLs should be understood by radiologists and radiographers.

DRLs should always be used in parallel with image quality evaluation (enough information for diagnosis shall be obtained).

Quantities used for DRLs should be easily measured. DRLs can be based on several quantities (e.g. entrance surface dose and entrance surface air kerma, DAP etc.) and parameters (such as fluoro time and number of images).
Diagnostic Reference Levels are not dose limits.

DRLs could be assimilated to investigation levels.

DRL are not applicable to individual patients. Comparison with DRL shall be only made using mean values of a sample of patients. DRLs should be a reasonable indication of doses for average sized patients.

The main objective of DRLs is their use in a dynamic and continuous process of optimization. DRL assessments should be carried out on a regular basis, at least every three - five years or as required by national legislation.
Dosimetry in: Digital and Conventional Radiology

- Methodologies followed to estimate patient radiation doses:
  - Doses can be **measured directly** by placing thermoluminiscent dosimeters (TLD) or diodes on the patients during the procedures.
  - Measure the kerma in air for all radiation beams and multiply it by the technique factors.
  - A properly calibrated **air-kerma-area-product (KAP)** meter (previously called DAP meter) attach to each x-ray machine.
  - **Manufacturer-dependent Dose values** (Exposure Index – EI)
  - Use **mathematical models to estimate internal dose**. Mathematical models based on **Monte Carlo simulations (PCXMC)**.
Use of DICOM information for patient dosimetry:

- Mammography units
  - Variations of AGD: ± 20%
- Angiography units
  - Variations: ± 40%

(Padovani IAEA presentation 2012)
Example on Calculating the Effective Dose using DICOM Header Information

- **For general X-ray done at DHA hospitals:**
  - PID- 88292... (Adult) DAP= 1.792 dGy cm² (as given in the DICOM header) = 0.1792 Gy cm² * 0.058 mSv/Gy cm² = **0.0104 mSv** (UK references quoted a figure of 0.033 mSv)

- **For CT done at DHA hospitals:**
  - PID- 88580... CTDI(vol)=19.mGy & DLP = 379.64 mGy cm (From CT Dose Report) * 0.0021 mSv/mGycm = **0.7972 mSv** (UK references quoted a figure of 1.6 mSv).
Managing Patient Dose in Digital Radiology

ICRP Publication 93
Ann. ICRP 34 (1), 2004

Abstract - Digital techniques have the potential to improve the practice of radiology but they also risk the overuse of radiation. The main advantages of digital imaging, i.e. wide dynamic range, post processing, multiple viewing options, and electronic transfer and archiving possibilities, are clear but overexposures can occur without an adverse impact on image quality. In conventional radiography, excessive exposure produces a black film. In digital systems, good images are obtained for a large range of doses. It is very easy to obtain (and delete) images with digital fluoroscopy systems, and there may be a tendency to obtain more images than necessary.

In digital radiology, higher patient dose usually means improved image quality, so a tendency to use higher patient doses than necessary could occur. Different medical imaging tasks require different levels of image quality, and doses that have no additional benefit for the clinical purpose should be avoided.

Image quality can be compromised by inappropriate levels of data compression and/or post processing techniques. All these new challenges should be part of the optimisation process and should be included in clinical and technical protocols.

Local diagnostic reference levels should be re-evaluated for digital imaging, and patient dose parameters should be displayed at the operator console. Frequent patient dose audits should occur when digital techniques are introduced. Training in the management of image quality and patient dose in digital radiology is necessary. Digital radiology will involve new regulations and invoke new challenges for practitioners. As digital images are easier to obtain and transmit, the justification criteria should be reinforced.

Commissioning of digital systems should involve clinical specialists, medical physicists, and radiographers to ensure that imaging capability and radiation dose management are integrated. Quality control requires new procedures and protocols (visualisation, transmission, and archiving of the images).
IAEA 1667, 2011:

It is not known yet whether the widespread introduction of DR techniques will also result in an increase in the use of x-ray examinations and hence will increase doses to patients and to population.

Hence, studies on frequency of radiological procedures are essential.
Dubai Health Authority (DHA) Experience

The DHA participated in national and regional projects under the umbrella of the International Atomic Energy Agency (IAEA).
Dubai Health Authority (DHA) Experience
1- General Radiology (Paediatric)/LH 2012

Patient Data Collection / Phantom Studies
The phantoms were designed for GR and Fluoro radiology practices and the patient data collection took place.

The phantoms were as:
Abdomen/Lumbar Phantom (ANSI)

**Phantom Material:**
Sheets of Perspex (PMMA)

**Phantom Thickness:**
4 sheets of PMMA each as 25 cm x 25 cm x 2.54 cm, total thickness 10.16 cm for Neonatal Paediatric Group

4 sheets of PMMA each as 25 cm x 25 cm x 2.54 cm & 1 PMMA 25 cm x 25 cm x 5.08, total thickness 15.24 cm for the 1m-10y Paediatric age group
• **X ray equipment:**
  - X ray unit and model: GR Siemens, Bucky Diagnost
  - Imaging using digital image receptor: Fujifilm
  - Image receptor model: FCR Capsula XL

* Upper diagnostic reference level expressed as entrance surface dose to the patient. The entrance surface dose for standard-sized patients is the absorbed dose in air (see explanation in Para. 7 on the use of air kerma vs absorbed dose to air) (mGy) at the point of intersection of the beam axis with the surface of a paediatric patient, backscatter radiation included.

Table 3.2. Variations of entrance surface dose* (converted to mGy, to the nearest two decimal places) observed in the three European Union paediatric trials (1989/91, 1992, 1994/95): median, minimum-maximum values and corresponding ratio (minimum:maximum) of frequent x-ray examinations in paediatric patients.

2nd ICRP International Symposium on the System of Radiological Protection
October 22-24, 2013, ABU DHABI, UAE
Step3*: Average Glandular Dose, DG:

- The measurements of the Entrance Surface Air Kerma \( K_{a,e} \) were performed in two steps. First, the ACR phantom was exposed to X-ray beams using automatic mode to get the \( kVp \), mAs, and target/filter combination used in each facility.
- Then, the phantom was removed and a similar exposure was performed in manual mode with no phantom.
- In some hospitals the manual mode was used instead of the automatic mode.
- Dedicated ionization chambers fitted to suitable Multimeters were utilized to measure the Incident Air Kerma. The value of \( K_{a,e} \), the Entrance Surface Air Kerma (ESAK) was deduced.

The Average Glandular Dose \( DG \) was calculated as:

\[
DG = K_{a,e} \cdot g \cdot c \cdot S
\]

\( g \): factor of glandularity of 50%
\( C \): corrects for the different breast composition
\( S \): correct for different choice of X-ray spectrum

The necessity for local radiation protection educational programs and patient dosimetry monitoring and recording were emerged from our patient radiation dosimetry projects. These are considered as essential requirements to prompt radiation safety culture within the various healthcare communities.

Conclusions:

- **Variation in dose measurements** along with the variation in manufacture specifications reflected on the **wide range of DRLs** values in radiological examinations.
- Well **established and simple methods in dose evaluation** for DR systems are required to avoid patient overexposure.
- No enough **DRLs data on IR procedures and on Paediatric group**.
- **CBCT DRLs data is not widely implemented** yet, however, some DRL figures already quoted.
- Patient radiation exposure **auditing** is to be considered as part of Quality Assurance program and this not been fully implemented at our area yet. This will improve patient radiation safety.
- Standardization of automated dose evaluation among the manufactures is required. **Automated DICOM dose extraction techniques** are essential to handle large samples of patients dosimetry data.
- **Lack of qualified experts and medical physicists** obstruct the process in research work related to patient radiation dosimetry and safety.
Conclusions:

**What Do We Need From ICRP In Medicine?**

- **Education**: Educate and Instruct Radiology teams to avoid overexposure and “**Dose Creep**” in DR practices.
- **Re-evaluation** of DRLs for DR procedures.
- **Simple methods** for patient dose evaluation.
- **Emphasis on Dose Recording** within patients medical reports
- **Dose Registry**: Uniform, Accurate & Calibrated

Source
1.Department of Medical Education, Dubai Health Authority, Dubai, United Arab Emirates.

Abstract

OBJECTIVE. Experience of continuous monitoring and control of patient doses in CT in Dubai Hospital over a period of approximately 4 years (January 2008 through August 2011) is presented. MATERIALS AND METHODS. Dose measurements— in particular, weighted and volumetric CT dose index, dose-length product (DLP), and estimated effective dose—were regularly monitored using head (16 cm diameter) and body (32 cm diameter) CT phantoms. Patient radiation dose indexes were manually recorded during 2008 for common CT examinations: head, chest, and abdomen and pelvis scans. In 2009-2011, these CT dose data were recorded within the radiology information system and the PACS. Dose reduction actions were taken while maintaining a watch on image quality. The effects of these factors were monitored through change in average DLP on a monthly basis and third quartile annually. Adapted diagnostic reference levels were used for comparison. RESULTS. The reduction in adult dose indexes in 2010 as compared with 2008 was 52%, 16.4%, and 34.8% for head, chest, and abdomen and pelvis examinations, respectively. For the pediatric group, the reduction was 45.23%, 39.6%, and 43.34% for head, chest, and abdomen and pelvis examinations, respectively. CONCLUSION. Substantial reduction in DLP for common examinations of adults and children is shown through a program of continuous monitoring and action. The results indicate the need to introduce local diagnostic reference levels to substitute for the adapted ones.
